Numerical evidence

One frozen joint-error event; different evidence routes

Complete finite law

Requires

The listed states and masses define the complete law.

Establishes

Exact risk and event probability when evaluated with exact arithmetic.

Still separate

Optimality needs a separate certificate for the declared family. Arithmetic does not validate the scientific law.

Fresh iid assessment

Requires

Freeze the complete event, sample size and assurance rule before fresh conditional iid states.

Establishes

A binomial rule can give conditional assurance for that joint event.

Still separate

A nonpassing rule is inconclusive. Mean safeguards, optimality and model adequacy need other evidence.

MCMC event history

Requires

Retain aligned whole states and their chain/time order for the frozen report.

Establishes

Empirical event frequencies and dependence diagnostics for the retained history.

Still separate

Zero hits do not prove zero probability. Disjoint chains do not establish conditional iid validation.
