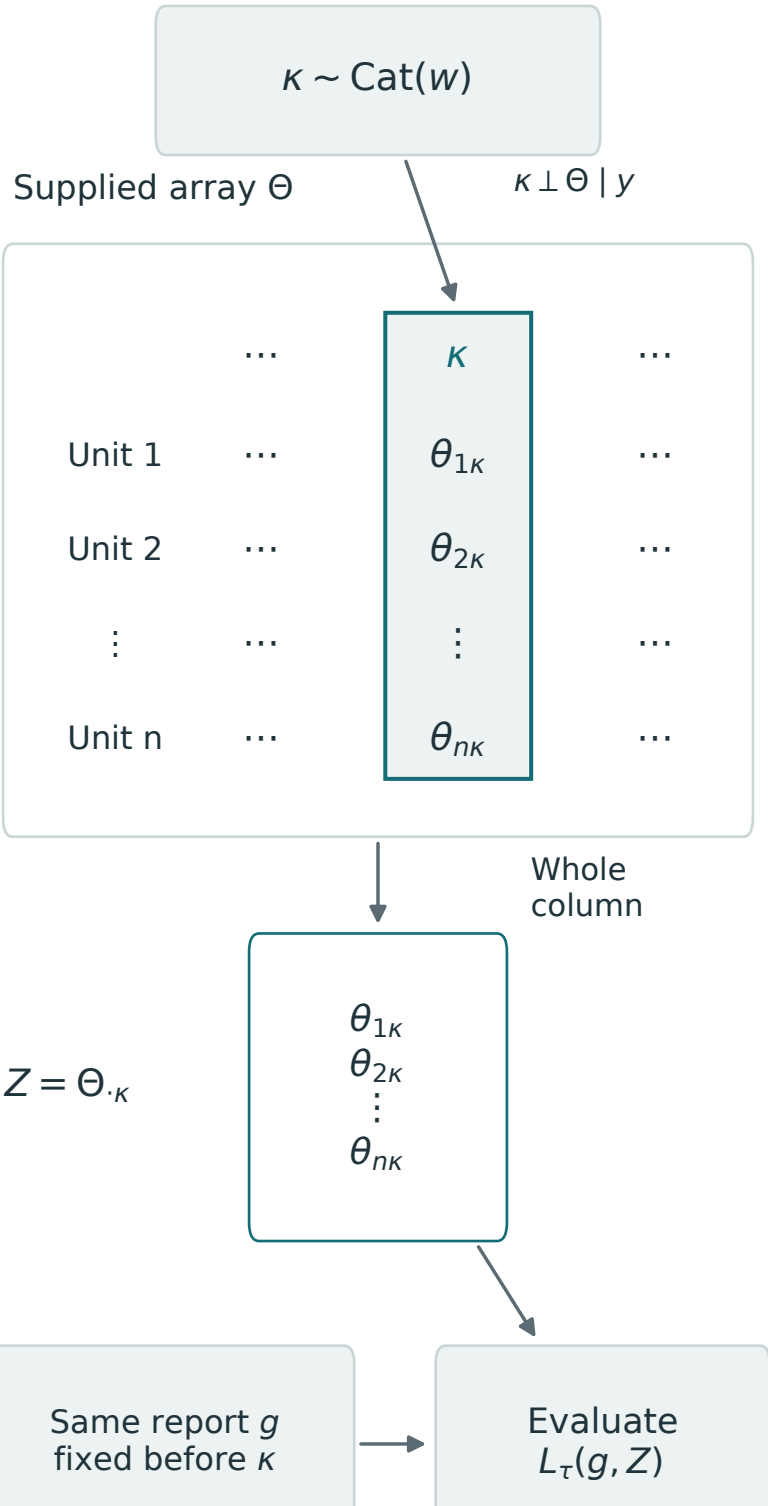
One selector chooses one whole vector

Fix y, weights w and the same report g before drawing the auxiliary criterion.



Same report g fixed before κ → Evaluate $L_\tau(g, Z)$

Whole-vector law

$$B_w = \sum_k w_k B_k$$

Weak-error mixture identity

$$E_{B_w}[L_\tau(g, Z) \mid y] = R^s_{w,\tau}(g \mid y)$$

Same g and feasible family.
Latent equality is allowed.

This mixes vector laws; no magnitude average of the targets is constructed.

Equality-neutral pair only
For one fixed pair:
Condition on distinct targets
in the selected criterion.
With positive distinct mass,
c^s_{ij}/δ^s_{ij} is the conditional error.
Conditioning generally reweights
which criterion is selected.
At zero distinct mass:
the ratio is undefined;
all three neutral pair costs are zero.
