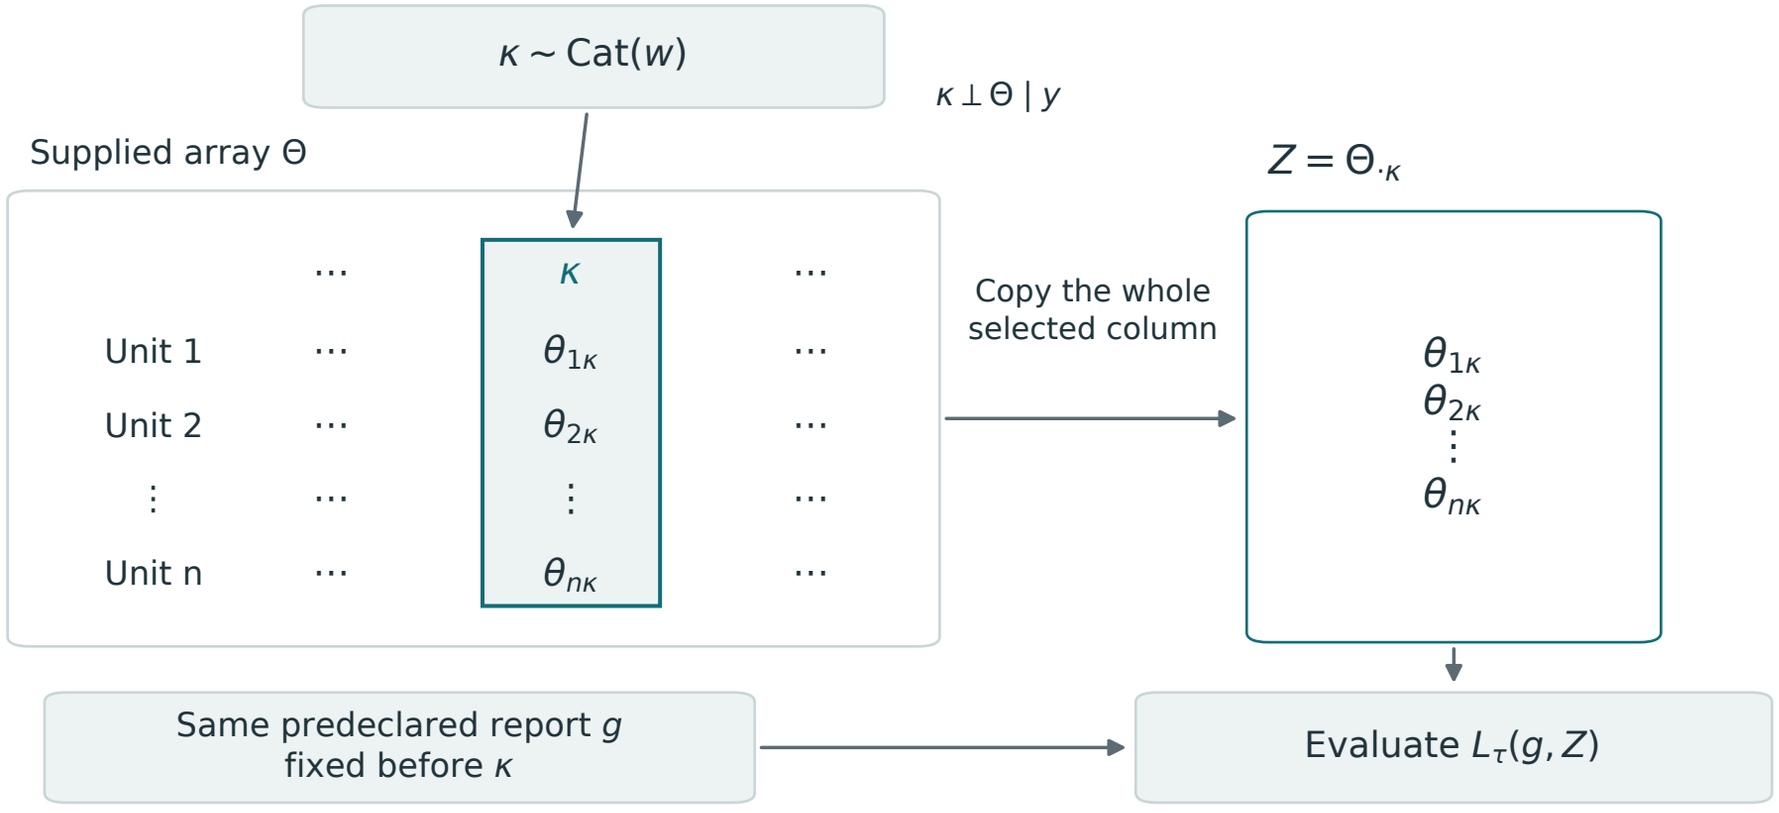
One selector chooses one whole vector

Fix observed information y, weights w and the same report g before the auxiliary draw.

Schematic array: arbitrary unit and criterion counts; within-column dependence is retained.



Whole-vector law: $B_w = \sum_k w_k B_k$

$$E_{B_w}[L_\tau(g, Z) \mid y] = R^s_{w,\tau}(g \mid y)$$

Same g, same feasible family; latent equality is allowed.

This mixes vector laws; no magnitude average of the targets is constructed.

Equality-neutral pair only: selected-coordinate distinctness, $\delta^s_{ij} > 0$

$$c^s_{ij}/\delta^s_{ij} = P(Z_i < Z_j \mid Z_i \neq Z_j, y) \qquad P(\kappa = k \mid Z_i \neq Z_j, y) = w_k d^s_{ij,k}/\delta^s_{ij}$$

At $\delta^s_{ij} = 0$, the ratio is undefined and all three neutral pair costs are zero.
