Select under one law; evaluate under another

Hold the decision problem fixed

Observed y, targets, loss, preferences, M and the same nonempty finite family F(y).

1. Choose under supplied beliefs

$\widehat{g} \in \mathcal{F}(y)$
$R^s(\widehat{g}) \le \min_{g \in \mathcal{F}} R^s(g) + \eta$
Actual selection-risk gap η ≥ 0.

2. Freeze the report

Same complete report ĝ.

3. Assess the same report

$\Pi_s(\cdot \mid y): \quad R^s(\widehat{g})$

$P(\cdot \mid y): \quad R^P(\widehat{g})$

P is a declared evaluation model; its correctness needs evidence.

Conditional comparison on that same family

$d = \max_{g \in \mathcal{F}} |R^s(g) - R^P(g)|, \qquad R^P(\widehat{g}) - \min_{g \in \mathcal{F}} R^P(g) \le 2d + \eta$

No value for d is supplied by the diagram; g minimizers stay within F(y).

Numerical approximation within one law

Approximate the same supplied law.
More draws can improve integration; they do not establish agreement with the evaluation law.

Discrepancy between laws

Requires evidence about the evaluation model.
Different laws can share relevant action risks.
Objective control does not transfer protection safety.

Equality-neutral loss also retains distinctness-dependent withholding. Law-specific guards must not silently change the common family.
Arrows depict calculation flow; no empirical calibration, causal effect or universally positive regret is asserted.
