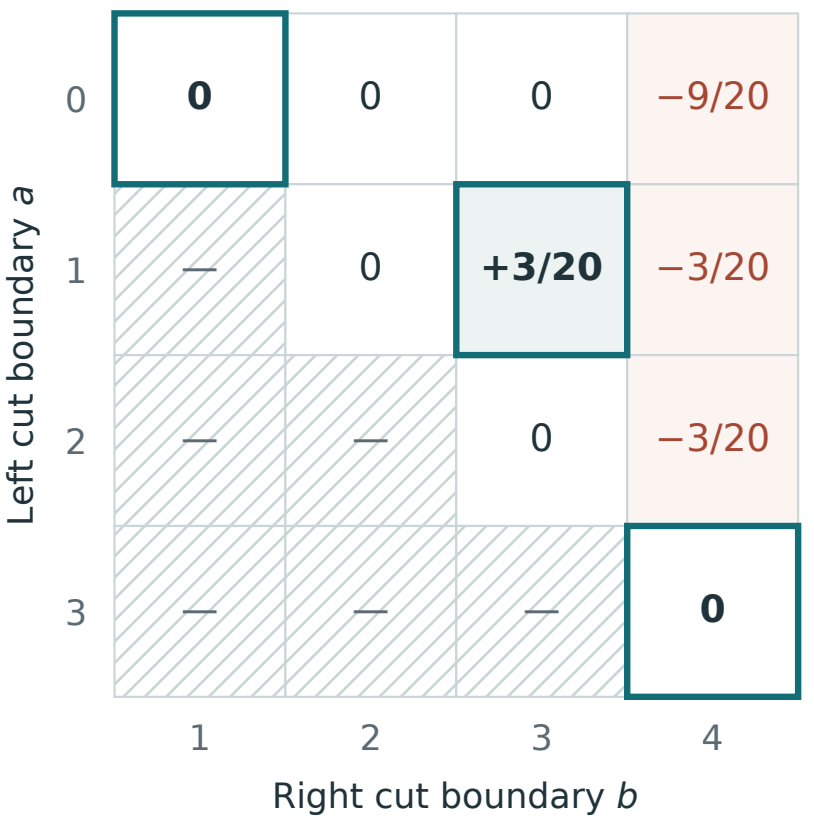
A dynamic program chooses grade boundaries

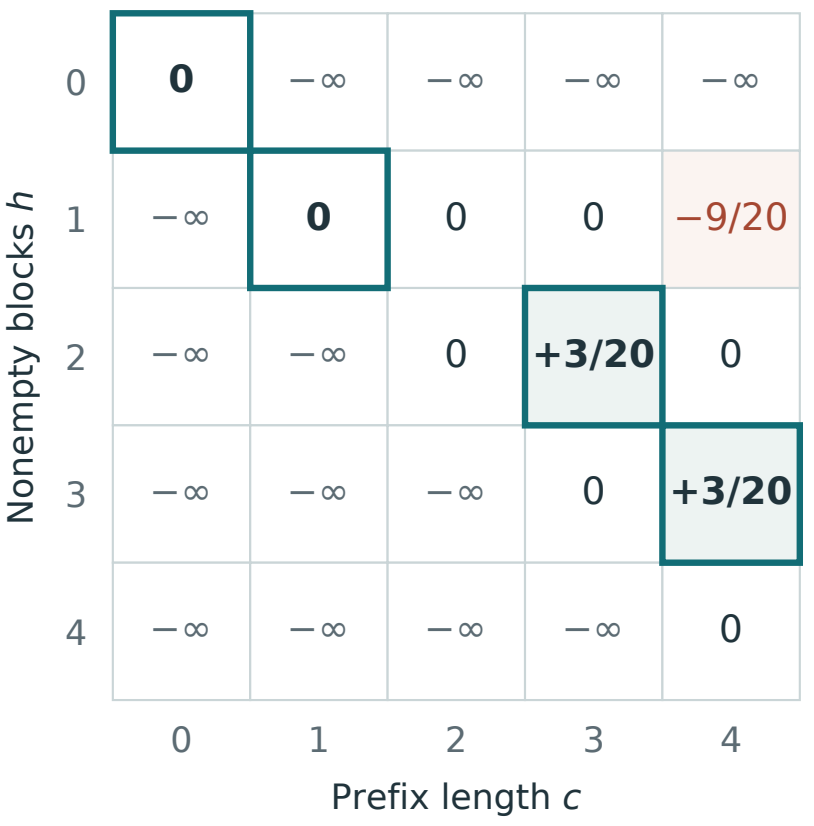
Fixed order: A, B, C, D.
w = (3/5, 2/5), τ = 1/4; M = 6.

(a) Signed interval savings $W(a, b)$



W(a,b) covers positions a+1 through b.
Signed savings may be negative.

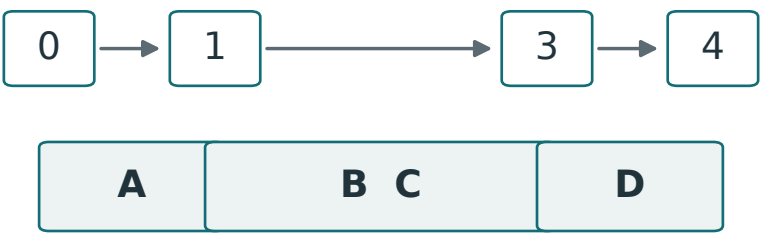
(b) Prefix maximum savings $V_h(c)$



−∞ is infeasible; $V_0(0)=0$ is auxiliary.

Maximum over the previous cut b:
$$V_h(c) = \max_b \{V_{h-1}(b) + W(b, c)\}$$
where $h - 1 \le b < c$.

(c) Recover the three-block report



$$g = (1, 2, 2, 3), \quad N = 5$$

Saving 3/20; risk reduction 1/40.

$$R = 7/40 - (3/20)/6 = 3/20$$

Exactly 4 grades
Risk 7/40

At most 4 grades
Risk 3/20

(d) Guarded neutral extension

Separate symbolic qualification

A full active-profile equality class H
must stay within one grade.

No cut may split H between
its first and last positions.

Use the neutral loss and its baseline.
Keep original units and pair multiplicities.

Separate from the tie-free example;
no package DP implementation is asserted.
